Coming Events – Ranges (Normal +/- Std Dev):
American plum borer
  1st flight subsides ................. 1211-1425 751-919
Apple maggot 1st catch ............. 1230-1632 785-1039
Codling moth 1st flight subsides. 1280-1858 811-1225
Comstock mealybug
  1st adult trap catch ............... 1308-1554 809-1015
Comstock mealybug
  1st flight peak .................... 1505-1731 931-1143
Lesser appleworm
  1st flight subsides ............... 990-1466 604-932
Lesser appleworm
2nd flight begins .................. 1418-2002  918-1326
OBLR summer larvae hatch .......... 1038-1460  625-957
Oriental fruit moth
  2nd flight begins .................. 1281-1491  788-968
Oriental fruit moth
  2nd flight peak ...................... 1455-1995  924-1342
Pandemis leafroller
  flight subsides ...................... 1412-1644  880-1052
Redbanded leafroller
  2nd flight begins ...................... 1244-1576  764-1028
Redbanded leafroller
  2nd flight peak ...................... 1546-1978  991-1323
STLM 2nd flight peak .................. 1368-1798  852-1196

PEST FOCUS

Spotted Tentiform Leafminer 2nd flight beginning
Obliquedbanded Leafroller estimated start of egg hatch in DD base 43°F after biofix – 360 DD; 25% egg hatch - 450 DD; 50% egg hatch - 630 DD. Current DD43 since biofix (June 13): 339.

Wayne Co: Obliquedbanded Leafroller DD43 since biofix (June 7): Sodus, 477; Williamson, 483; Farmington, 478.

Highland: San Jose Scale damage (red dot) observed on fruit.
1st Apple Maggot trap catch.
Obliquedbanded Leafroller DD43 since biofix (June 1): 632; surface feeding on fruit observed.
Tent Caterpillar feeding observed.

ORCHARD RADAR DIGEST

[Box Text: AT YOUR SURFACE]

[M = Marlboro, Ulster Co.; G = Geneva]
Roundheaded Appletree Borer
Peak RAB egglaying period roughly: June 17 to June 30 [M]/June 25 to July 9 [G].
First RAB eggs hatch roughly: June 14 [M]/June 22 [G].
Peak RAB hatch: July 2 to July 20 [M].

Codling Moth
1st generation CM development as of June 27: 1st gen adult emergence at 100% [M]/98% [G] and 1st gen egg hatch at 94% [M]/77% [G].

Lesser Appleworm
2nd LAW flight begins around: July 2 [M].

Obliquebanded Leafroller
Where waiting to sample late instar OBLR larvae is not an option (= where OBLR is known to be a problem, and will be managed with an insecticide against young larvae) – Early egg hatch and optimum date for initial application of an effective insecticide: June 16 [M]/June 25 [G].
Optimum sample date for late instar summer generation OBLR larvae: June 25 [M]/July 4 [G].

Oriental Fruit Moth
2nd generation OFM flight begins around: June 20 [M]/June 29 [G].
2nd generation – first treatent date, if needed: June 28 [M]/July 7 [G].

Redbanded Leafroller
2nd RLBR flight begins around: June 21 [M]/July 1 [G].
Obliquebanded Leafroller

Assuming a biofix (1st adult catch) of OBLR anywhere from about June 1–13 (see the Pest Focus section), sites around the state have accumulated a total of 350-630 DD (base 43°F) as of this morning, which means that most areas will soon reach the 600 DD point in the insect's development that roughly corresponds to 50% egg hatch. This is the period during which the earliest emerging larvae begin to reach the middle instars that are large enough to start doing noticeable damage to foliar terminals and, eventually, the young fruits. This is also the earliest point at which visual inspection for the larvae is practical, so sampling for evidence of a treatable OBLR infestation is recommended now in orchards where pressure has not been high enough to justify a preventive spray already.

Guidelines for sampling OBLR terminal infestations can be found on p. 69 in the Recommends, using a 3%
action threshold that would lead to a recommended spray of an effective leafroller material. Delegate, Belt, Altacor and Proclaim are our preferred choices in most cases; Rimon, Intrepid, a B.t. material or a pyrethroid are also options, depending on block history and previous spray efficacy against specific populations. If the average percentage of terminals infested with live larvae is less than 3%, no treatment is required at this time, but another sample should be taken three to five days (100 DD) later, to be sure populations were not underestimated.

**Green Aphids**

Although small numbers of green aphids (Spirea aphid, *Aphis spiraecola*, and Apple aphid, *Aphis pomi*) may have been present on trees early in the season, populations have been increasing regularly as the summer weather patterns gradually become established. Both species are common during the summer in most N.Y. orchards, although no extensive surveys have been done to compare their relative abundance in different production areas throughout the season. It's generally assumed that infestations in our area are mostly Spirea aphid.
Nymphs and adults suck sap from growing terminals and water sprouts. High populations cause leaves to curl and may stunt shoot growth on young trees. Aphids excrete large amounts of honeydew, which collects on fruit and foliage. Sooty mold fungi that develop on honeydew cause the fruit to turn black, reducing its quality.

Aphids should be sampled several times throughout this season starting now. Inspect 10 rapidly growing terminals from each of 5 trees throughout the orchard, noting the percentage of infested terminals, including rosy aphid-infestations, since they tend to affect the foliage similarly to the green species at this time of the year. No formal studies have been done to develop an economic threshold for aphids in N.Y. orchards. Currently, treatment is recommended if 30% of the terminals are infested with either species of aphid, or at 50% terminal infestation and less than 20% of the terminals with predators (below). An alternative threshold is given as 10% of the fruits exhibiting either aphids or honeydew.

The larvae of syrphid (hoverflies) and cecidomyiid flies (midges) prey on aphids throughout the summer. These predators complete about three generations
during the summer. Most insecticides are somewhat toxic to these two predators, and they usually cannot build up sufficient numbers to control aphids adequately in regularly sprayed orchards. Check Tables 7.1.1 (p. 61) and 7.1.2 (p. 63) in the Recommends for ratings of efficacy and impact on beneficials for common spray materials. Both aphid species are resistant to most organophosphates, but materials in other chemical classes that control these pests effectively include: Asana, Assail, Aza-Direct, Beleaf, Calypso, Danitol, Lannate, Leverage, Movento, M-Pede, Proaxis, Provado, Pyrenone, Thionex, Voliam Xpress, Vydate and Warrior.

Woolly Apple Aphid

WAA colonizes both aboveground parts of the apple tree and the roots and commonly overwinters on the roots. In the spring, nymphs crawl up on apple trees from the roots to initiate aerial colonies. Colonies initially build up on the inside of the canopy on sites such as wounds or pruning scars and later become numerous in the outer portion of the tree canopy, usually during late July to early August. Refer to the June 6 issue of Scaffolds for an overview of some control recommendations.
**Potato leafhopper**

PLH is generally a more serious problem in the Hudson Valley than in western New York or the Champlain Valley; however, healthy populations can being found in WNY as well this season. Refer to the May 31 issue of Scaffolds for an overview of its biology and some control recommendations.

**Japanese Beetle**

This perennial pest overwinters as a partially grown grub in the soil below the frost line. In the spring the grub resumes feeding, primarily on the roots of grasses, and then pupates near the soil surface. Adults begin to emerge during the first week of July in upstate N.Y., so this activity could be starting this week in the Hudson Valley and other warmer sites. The adults fly to any of 300 species of trees and shrubs to feed; upon emergence, they usually feed on the foliage and flowers of low-growing plants such as roses, grapes, and shrubs, and later on tree foliage. On tree leaves, beetles devour the tissue between the veins, leaving a lacelike skeleton. Severely injured leaves turn brown and often drop. Adults are most active during the warmest parts of the day and prefer to feed on plants that are fully exposed to the sun.
Although damage to peaches is most commonly noted in our area, the fruits of apple, cherry, peach and plum trees may also be attacked, all of which have been suffering increasing damage from these insects in recent years. Fruits that mature before the beetles are abundant, such as cherries, may escape injury. Ripening or diseased fruit is particularly attractive to the beetles. Pheromone traps are available and can be hung in the orchard in early July to detect the beetles' presence; these products are generally NOT effective at trapping out the beetles. Fruit and foliage may be protected from damage by spraying an insecticide such as Assail, Calypso, Sevin or Voliam Xpress (in apple) or Assail, Leverage, Provado, Sevin, or Voliam Xpress in cherries or peaches) when the first beetles appear.
